MARCH 15, 1940

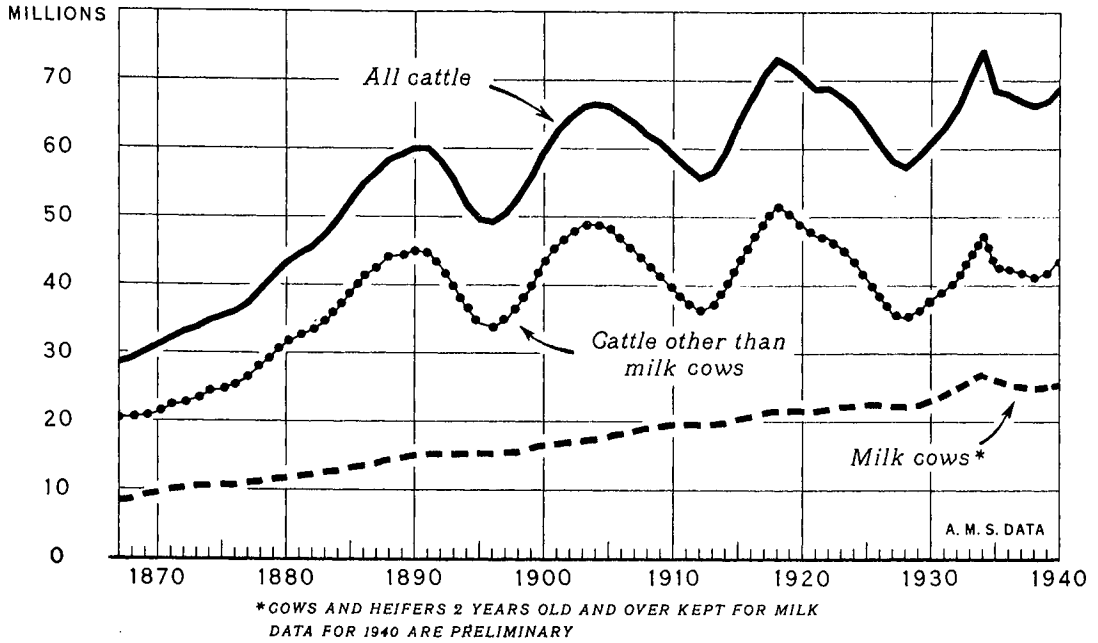

THE DAIRY SITUATION

COWS, HEIFERS, AND CALVES BEING KEPT FOR MILK
COWS, UNITED STATES, JAN. 1, 1920-JAN. 1, 1940

DROUGHT AND FEED SHORTAGE CAUSED HEAVY SLAUGHTER OF BOTH COWS AND YOUNG STOCK FROM 1934 UNTIL LATE 1937, AND THE NUMBER OF COWS AND CALVES ON FARMS WAS REDUCED MATERIALLY IN THIS PERIOD. FROM JANUARY 1, 1938 TO JANUARY 1, 1940 THE NUMBER OF MILK COWS INCREASED 2 PERCENT, AND THE NUMBER OF HEIFERS (1 TO 2 YEARS OLD) INCREASED 11 PERCENT. THE NUMBER OF YOUNG STOCK IS HIGH IN RELATION TO THE NUMBER OF COWS.

Summary

Further increases in the number of milk cows on farms are in prospect during 1940 and 1941 unless weather conditions should be unusually adverse. The number of heifers and heifer calves has increased rapidly and is more than enough to provide for normal replacements to dairy herds during the next 2 years. The number of milk cows on farms (25,334,000 head on January 1, 1940) has increased 1 percent in each of the past 2 years.

The increase in milk production during February was the largest on record, in contrast to the unusually small increase in January. The marked February increase, together with the general decline in business activity, was the principal cause of the sharp break in prices during the month. Total milk production on March 1 was estimated at nearly 3 percent larger than on the same date last year, and a new production record for this date is indicated. In view of the increased number of cows and fairly ample supplies of feed, production probably will continue at record or near record levels.

Prices of manufactured dairy products reached the winter peak in late January and early February, but then declined sharply. In late February and early March the Federal Surplus Commodities Corporation and the Dairy Products Marketing Association both purchased butter on the open market. Prices are now much below the winter peak, but they are decidedly higher than a year ago. Butter prices probably will continue higher than a year earlier during the remainder of the feeding period and also during the storage season this coming summer. The general level of prices is higher than a year ago, business is better, and storage stocks are lower. These factors will more than offset the effect upon butter prices of some increase in production.

Total production of manufactured dairy products in January was 1 percent above the preceding high for the month. Total receipts of milk and cream at the principal eastern markets in January were only slightly higher than in January 1939. Apparent consumption of the principal manufactured dairy products in January 1940 was 4 percent higher than in January 1939 and 3 percent above the preceding high for the month in 1934. The increase in consumption, together with the higher level of retail prices of dairy products, indicates a marked increase in consumer expenditures for dairy products.

Storage stocks of dairy products are much lower than a year ago and are approaching the seasonal low point for the year which usually occurs in May.

Price down sharply

The price of 92-score butter at New York reached the peak for the winter of 32.5 cents during the week ended February 4. By the week ended March 2, however, the price had dropped 4 cents to 28.5 cents. Cheese prices on the Wisconsin Cheese Exchange declined 2 cents per pound during the same period. The Dairy Products Marketing Association and Federal Surplus Commodities Corporation started to purchase butter on February 28, and during the period February 28 to March 9 purchased about 1,400,000 pounds. The sharp increase in milk production during February and the decline in business since December were the principal factors resulting in the sharp break in butter prices.

The price of butter in early March of 28.5 cents compares with the average of 24.3 for March 1939.

The price of butterfat is somewhat below average compared with feeds, but is decidedly above average compared with hogs. The recent drop in butter prices has not altered the outlook for continued heavy production.

Milk production up sharply

Milk production per cow as reported by crop correspondents on March 1 was nearly 2 percent higher than on March 1, 1939 and equal to the preceding peak for that date a decade earlier. This increase in production per cow, together with the increase in cow numbers, indicates that total milk production on March 1 established a new high, nearly 3 percent larger than production a year earlier. On a per capita basis milk production on March 1 was the highest since 1932 and 6 percent above the 1925-29 average for March 1.

The increase in milk production from February 1 to March 1 was exceptionally large, in contrast to the small increase during January. It seems probable that milk production will continue at record or near record levels during the remainder of the feeding period.

Manufactured production large

Total production of the principal manufactured dairy products in January established a new high for the month. It was 1 percent above the preceding high for the month in 1939, and it was 11 percent larger than in November. This was about the same as the usual seasonal increase between these 2 months. On a per capita basis, production in January was 13 percent above the 1924-29 average.

Production of creamery butter in January was slightly less than in the same month of 1939. Cheese production, however, was up 3 percent, and evaporated milk production was up 21 percent. Output of evaporated milk established a new high for the month, but production of both butter and cheese was somewhat below the preceding highs established in 1933 and 1939 respectively.

Production of manufactured dairy products is likely to continue high in relation to other recent years.

Fluid milk receipts up

Average daily receipts of milk at New York, Boston, and Philadelphia during January were 1 percent higher than a year earlier and the highest for the month in the 11 years of record. Cream receipts also were up about 1 percent, and were the highest for the month since 1937. There was also a marked increase in the receipts of fresh condensed milk in bulk. On a milk-equivalent basis, receipts of these three products were about 1 percent higher than a year earlier. The increase from December to January, however, was somewhat less than the usual seasonal increase.

Trade output high

Apparent consumption of creamery butter in January was 5 percent larger than in January 1939. This increase occurred even though there was a marked reduction in the distribution of butter for relief. Trade output through regular commercial channels was about 13 percent larger than a year earlier. This increase in consumption was accompanied by higher retail prices. Indicated consumer expenditures for butter in January were 20 percent larger than in January 1939.

Apparent consumption of cheese in January was slightly above the preceding high for the month in 1939. Retail prices of cheese in January were about 2 percent higher than a year earlier. These changes indicate an increase in consumer expenditures of about 4 percent.

Trade output of evaporated milk was up about 1 percent from January last year. This was the first month that the trade output of evaporated milk was larger than a year earlier since the heavy forward buying occurred last September. Retail prices were up 3 percent.

Total consumption of manufactured dairy products in January was 4 percent greater than a year earlier, and 5 percent above the preceding peak for the month in 1934.

* * * * *

NUMBER OF MILK COWS, 1920-40

The number of milk cows on farms increased 1 percent in 1938, an additional 1 percent in 1939, and further increases during 1940 and 1941 are in prospect, since the number of heifers and heifer calves on farms is high in relation to the number of cows and is more than enough to provide for normal replacements to dairy herds in 1940 and 1941. On January 1, 1940 there were 25,334,000 head of milk cows (cows 2-years-old-and-over kept for milk) on farms. This is the largest number since 1936, and has been exceeded only during the 4 years 1933-36.

While the number of cows is high in relation to other years, it is not unusually high compared with the number of people. In the 15-year period 1920-34 there were on the average 19.7 cows per 100 people in the country. In 1928, when milk cow numbers were low, there were only 18.7 per 100 people. With the rapid increase in cow numbers from 1928 to 1934, the number per 100 population increased to 21.3. On January 1, 1940, there were 19.3 cows per 100 people. This is somewhat below the long-time average but higher than in the period 1927-30 and 1938-39. With the increases in number of milk cows in prospect it is quite probable that the number per capita will again exceed the long-time average.

More striking than the increase in the number of milk cows has been the rise in the number of young stock. On January 1, 1940 there were 5,433,000 head of heifers 1-2 years old (being kept for milk cows) on farms. This was 6 percent more than a year earlier and 11 percent more than 2 years earlier. The number of heifers is not only large compared with other years, but is the highest on record in relation to the number of cows. On the basis of the inventory of numbers at the beginning and end of the year, there were 4,879,000 head of cows eliminated from herds during 1939. During the past 5 years culling has averaged 5,094,000 head per year. Thus the number of heifers (1 - 2 years old) on hand January 1, 1940 is larger than the average number of cows and heifers eliminated from herds during the past 5 years.

The number of heifer calves (being kept for milk cows) on farms January 1, 1940 which ordinarily would be added to milking herds in 1941 is also relatively high in relation to the number of cows, and appears to be more than enough to provide for replacements to herds in 1941. An upward trend in milk cow numbers until 1942 seems assured, unless adverse weather should cause a liquidation of dairy herds.

The tendency for milk cow numbers to increase in the past 2 years has been widespread. There were only 6 States, Missouri, Kentucky, Texas, Utah, Colorado, and Oregon, in which numbers declined, and in no case was the decline more than 3 percent. In 3 States there was no change; in 39 States increases occurred. Numbers have increased in each of the major sections of the country. (See table 2.) The number of young stock in relation to the number of cows is also relatively high in all sections of the country. (Table 3.)

During the past 50 years there have been marked cycles in the total number of cattle on farms, but there has been a rather steady upward trend in the number of milk cows. The total number of cattle was low in 1896, 1912,

1928, and 1938. Following the low points in 1896, 1912, and 1928 total cattle numbers increased about 7 percent in 2 years. In the past 2 years numbers increased only 4 percent. (Table 4.) The number of milk cows, however, has increased nearly as rapidly as in other periods of increasing numbers.

1/ Cows and heifers 2 years old and over kept for milk.

2/ Being kept for milk cows.

3/ Number eliminated equals number of cows first of the year plus number of heifers (1 to 2) minus number of cows at the first of the following year. The number eliminated includes death losses, farm slaughter, culling, sales to non-farm families, and the net shift in "kept for milk" to beef classification.

4/ Average for 1935-37.

During the past year prices of cattle and milk cows have been high in relation to other products. The increasing numbers of cattle that are under way will tend to depress prices of cattle in relation to other commodities. If the general level of prices stays about where it is, the price of cows would be expected to decline. If the general level of prices rises, however, prices of milk cows might not decline but would not rise as much as the general average.

E. E. VIAL.
